

Digital supplementary material to

MOLERO-BALTANÁS, R., BACH DE ROCA, C., TINAUT, A., DIZ PÉREZ, J. & GAJU-RICART, M. 2017: Symbiotic relationships between silverfish (Zygentoma: Lepismatidae, Nicoletiidae) and ants (Hymenoptera: Formicidae) in the Western Palaearctic. A quantitative analysis of data from Spain. – Myrmecological News 24: 107-122.

Appendix S1: Zygentoma hosted by ants in the Western Palaearctic region (Europe, North Africa and Macaronesian region). Tables integrate data of literature with new data generated in this work.

In this document, two types of tables are presented:

- 1) Summary of interactions of each ant genus with various species of Zygentoma.
- 2) Details of interactions of each ant species with various species of Zygentoma (giving the references to literature and the data of the new samples studied).

These two types are condensed in a single table for those genera where only one species is reported (or where no specific identification of the ant is available).

The references included in the tables that are not in the main article are detailed at the end of this file. Before the list of references of this Appendix, an additional table (Table S1.73) includes previously published data on the associations analysed in this work.

Remarks for all tables:

Abbreviations of species of Zygentoma as in Table 4 of the main article.

Other abbreviations given in tables:

Tot.: Total number of samples studied in Spain (published or reported in this work).

Lit est.: Number of samples previously published and included in the statistical study made in Spain (presented in the main paper).

Lit not incl.: Number of samples mentioned in the literature of Western-Palaearctic Zygentoma and not included in the statistic study of Spain (mainly published by other authors and for other countries).

The references to Molero-Baltanás are abbreviated to Molero. The references to Bach de Roca and Gaju-Ricart are also abbreviated to Bach and Gaju, respectively.

New interactions are highlighted in the tables with bold characters and grey background.

Detailed references tables for each ant species include the name of the author(s) and the year of publication for each interaction in the literature. The number of samples included in each reference is given in brackets. Literature references not included in the statistical study of the main article are marked with an asterisk. For new data, tables of each ant species include the locality, date, number of specimens (M = males, F = females, J = juveniles) and the reference in the collection of the Universidad de Córdoba (UCO) where they are deposited. In these tables, the bold character means new interactions (reported here for the first time).

Species and genera authorities are given only when they are not mentioned in the main article.

Interactions of silverfish with ants identified at the generic level are not considered new unless there is no other reference of the silverfish with another ant species of the same genus.

Tab. S1.1: Numbers of the different types of interaction of *Aphaenogaster* ants with silverfish. 35 different types of interactions, 30 of them reported in Spain, nine of them new. 77 interactions from samples of Spain for statistic study (47 of them previously published), 40 additional Western-Palaearctic interactions from literature not included in statistics.

<i>Aphaenogaster</i> species	Av	Pp	Lb	Lc	Ls	Ner	Ncu	Nd	Nf	Nh	Nl	Np	Nsp	Nw	Tot	Lit stat	Lit not incl

Tab. S1.38: Interactions of ants of the genus *Goniomma* EMERY, 1895 with silverfish. *Goniomma blandi*: This is the first time, as far as we know, that a Zygentoma is reported in a nest of this genus of ants. The sample was published in MOLERO & al. (1992), but in this work no reference to the ant was indicated. So at this moment the interaction is referred as new. This interaction is not included in Tables 2 and S2.1, but in Table 5 of the main document, since the specimen of Lepismatinae was in bad condition and it was not possible to identify it at species level.

Species of Zygentoma (number of samples)	Literature references	New data
<i>Neoasterolepisma</i> sp. (1)		Granada, road from Guadix to Baza ($37^{\circ} 23' N, 3^{\circ} 01' W$), 21-6-86. 1F. Ref. Z0215.

Tab. S1.39: Number of the different types of interaction of ants of the genus *Lasius* FABRICIUS, 1804 with silverfish. Thirteen types of interactions, ten of them reported in Spain, one of them new. Nineteen interactions from samples of Spain for statistic study (18 of them previously published), twelve additional Western-Palaearctic data of interactions from literature not included in statistics.

<i>Lasius</i> species	Av	Pp	Ls	Ncu	Nh	Nw	Tot	Lit stat	Lit not incl
<i>Lasius alienus</i>		1					1	1	2
<i>L. brunneus</i>		5					5	5	1

Summary

193 Zygentoma-Formicoidea associations are included. 157 of them have been detected in Spain; 41 of them are new (reported for the first time). 834 samples from Spain have been included in the statistical study of the main paper, 398 of them previously published (included in papers detailed in Table S1.73).

225 additonal samples or references included in the literature are taken into account but not included into the statistic study. In total, 1059 reports of interactions Zygentoma-ants in the West Palaearctic Region have been considered for conclusions of this work.

Tab. S1.73: Papers where samples of silverfish with ants in Spain have been previously reported by the authors. All of them are considered for the analysis of the main paper, together with new data given in this Appendix. (* = geographic coordinates and/or maps are given in the paper).

A) Results of the sampling carried out in Spain for the quantitative analysis

Data registered in Table S2.1 correspond to the number of nests of each species of ants where each species of Zygentoma was found. Nests in which the species of Zygentoma were not identified at the specific level are not included in this Table (for example, those in which the silverfish was only identified as *Neosteroolepisma* sp.).

Overall, 156 different associations are registered. Those highlighted in bold characters and grey background are new associations (i.e., reported for the first time in this work). Additionally, one association has been detected but not included in this table: the finding of *Neoasterolepisma* sp. in a nest of *Goniomma blanci* (because the silverfish of the sample could not be identified at species level, the association has not been included in this table). In this sample (see reference in Table S1.38 of the Appendix S1), the specimens were in poor condition. This is the first time that *Goniomma* is reported with silverfish, so we can account it as association number 157 and it is included in Table 5 of the main document, where all colonies with silverfish were considered.

B) Reasons to group species of ants by genus (Table 2 of the main document)

Formicidae species were grouped by genus:

- To provide the best significance to analyses;
 - to obtain an ecological network with a higher level of connectance.
 - Some ant species are not abundant but grouped by genus; they are frequent enough to make the assumption of their overall availability for silverfish choice along the territory (see later in this appendix).
 - This grouping is possible because in biological terms, it makes sense, since the species of the same genus are evolutionarily related, show similar biological trends and seem to be preferred in the same way for silverfish species, as the correspondence analysis confirms.

C) Complementary sampling used for testing the influence of the relative abundance of ants in the preference of silverfish

Methods: The sampling was made in eight localities of Spain (LOC 1 to LOC8), following the same method described in the section “Material and methods” of the main text of our paper, with some differences:

- 1) All ant colonies found were counted, those where *Zygentoma* were found (WZ) and those without any silverfish (NO-Z).
 - 2) Ants were identified at the generic level in the field but silverfish were not identified. When the identification was possible *in situ*, ants were not collected.
 - 3) The duration of each sampling was 80 minutes (more time than usual samplings in order to add the time for recording the additional data).

Results: Data are presented in Tables S2.2, S2.3, S2.4 and S2.5.

The proportion and contingency table Chi squared test was made from the total numbers of the eight localities because the number of nests per locality was not high enough for separate testing. Nevertheless, the sample size is insufficient to give a definitive conclusion. The data included here must be taken as trends to be confirmed with greater samples.

As Table S2.2 shows, the total WZ column shows a higher number of nests of *Messor* compared with the rest of ant genera found, even when *Messor* are not more abundant than other genera, as the total absolute frequencies of most localities or the total NO-Z column indicate.

To state whether the distribution of ant nests is homogeneous between NO-Z and WZ categories, a Chi squared test should be done to the respective contingency table, and to state if the proportion of *Messor* nests with silverfish is significantly higher than in any other ant genus, a proportion test should be made. However, in both cases, the expected frequencies are too low to consider the significance definitive.

Despite the previous consideration, several trends can be observed: some abundant ants as *Pheidole* (15.9% of the total), *Tapinoma* (13.7% of the total) and the category “Others” (17.2% of the total; see Table S2.3) host silverfish in very low rates, as can be seen in Table S2.4. Only 11.1% of *Pheidole* nests hosted silverfish, and none of *Tapinoma*. Moreover, the Total category shows also very low percentages compared with *Messor*, *Cataglyphis*, *Aphaenogaster* or *Formica*, all of them less abundant in the sampling but occupied by Zygentoma in greater proportions.

These remarks are supported by Table S2.4 and allow the results to be considered a probable trend: the relative abundance of ants does not have an influence in silverfish preferences for choosing a certain ant genus. We started our samplings assuming that the nests of most ant genera are available throughout most of the territory to the choice of silverfish.

The present study is focused on the detection of different degrees of specialisation and on different modes of the Zygentoma-ant association and not in other considerations that can be important for mutualistic networks. From this point of view, if results are biased by silverfish preferences, it is not important to make an account of all colonies in a locality, but only those where the association is detected. Compared with the more studied plant-pollinators networks, the aim of our work is not to know how many flowers (nests) of a given species/genus of plants (ants) are available for a pollinator (silverfish) species, but how many are actually visited (occupied). In our quantitative “symbiotic” network, numbers (especially those of *Messor*) do not reflect ant abundance, but silverfish preferences (conditioned by some features of ant and silverfish biology, but not by demographic factors of ants).

Table S2.2: Results, in absolute numbers, of the complementary sampling of 8 localities (LOC 1 to LOC 8) and total nests of each genus of ants. The number of nests with (WZ) or without Zygentoma (No-Z) is distinguished in separate columns. Details of localities are given in Table S2.6.

Ant genus	LOC 1		LOC 2		LOC 3		LOC 4		LOC 5		LOC 6		LOC 7		LOC 8		Subtotal		Total

Appendix S3

Table S3.1: States of characters for cladistic study of Spanish Lepismatinae (*Lepisma*, *Neoasterolepisma*, and *Tricholepisma*).

Table S3.2: Characters and states. * The number 1 has been used for the apomorphic condition, but in those characters where gradual differences can be distinguished, two states have been indicated with numbers 1 and 2.

Character	Plesiomorphic condition (0)	Apomorphic condition (1 and 2)*
C.1. Isolated macrosetae in urotergites	Absent (macrosetae arranged in combs)	Present
C.2. Body shape	Fusiform (thorax slightly wider than abdomen)	Slightly limuloid (thorax very wide respect to abdomen base) (1) or very limuloid (paranotal lobes very developed) (2)
C.3. Yellowish epidermic pigment	Absent	Present
C.4. Golden scales	Absent (most scales silvery grey, black or brown)	Present, but in most specimens most scales are greyish (1) or all scales are golden (only they sometimes get dark before molt) (2)
C.5. Asteriform sensilla in antennae	Absent	Present
C.6. Asteriform sensilla of antennae arranged in pairs in some joints	No	Yes
C.7. Hind tibiae of males modified in shape	No	Yes
C.8. Hind border of nota with isolated macrosetae	No	Yes
C.9. Urosternites with pseudostyli	No	Yes
C.10. Shape of dorsal scales	Rounded	Rounded and acute
C.11. Hind border of posterior urosternites with spiniform macrosetae	No	Yes
C.12. Chaetotaxy in urotergites (except infralateral group)	2 x (1+1+1)	Modified
C.13. Chaetotaxy of the labial palp in the male	Normal	Modified
C.14. Hind tibiae of males with ciliar setae	No	Yes
C.15. Infralateral group of macrosetae with a fine outer setae	Yes	No
C.16. Isolated setae in urotergite I	1+1	More than 1+1
C.17. Isolated setae in urotergite IX	Absent	Present
C.18. Number of macrosetae in infralateral groups	2+2 (or more)	1+1
C.19. Spiniform setae in hind tibiae of the male	No	Yes
C.20. Paramera	Big, very developed	Small, reduced
C.21. Rows of white scales on hind borders of nota	No	Yes
C.22. Lost of pigment on eyes	No	Yes
C.23. Reduction of size	No	Yes
C.24. Number of macrosetae of the infralateral group of urotergites	Two (or more)	One

We included all the features that we could. None of the characters that allow distinguishing between Lepismatinae species has been discarded. Usually, these are included in descriptions and identification keys of this group of insects, as can be seen in the taxonomic works included in Table S1.73 in Appendix 1. Among them, some can be considered general traits and others have a putative relevance for living with ants. All the morphologic characters that can be used to reconstruct the evolution of this group have been included. Therefore, there is no reason to infer that the cladogram of Figure 12 is biased. The outgroup (*Allacrotelsa*) is a clearly primitive genus of Lepismatidae found in Palaearctic and

Nearctic regions (and in Baltic amber), whilst the remaining genera and species are exclusive of the Old World (evolved after the break-up of Gondwana).

In relation to the evolutionary significance of the 24 characters listed in the Tables of this Appendix, we can establish the following hypotheses:

- The significance of some of these characters in order to associate with ants is not clear (i.e., characters 1, 8, 13, 16, 17, 18, 21, and 24).
- The apomorphic condition of some of them (i.e., 1, 8, 20, 22, and 23) is shared with non-myrmecophile Zygentoma, suggesting that they must be related with other evolutionary trends of silverfish.
- The apomorphic condition of some of them probably represents a usual adaptation of Zygentoma to live with ants, since they are shared with most Atelurinae (i.e., 2, 3, and 4), but not all myrmecophile Lepismatinae develop this condition.
- One of these features might be considered a pre-adaptation related to living with ants (5), since it is present in non-myrmecophile species of the genus *Neoasterolepisma*, but its role is not clear.
- The apomorphic state of some other traits is not present in all myrmecophile Lepismatinae, but only shared by several *Messor* and *Aphaenogaster* specialists (i.e., 7 and 14) or by few species of *Messor* specialists (i.e., 9, 10, and 11). It is likely that some of these latter characteristics are not important for adapting to life with ants but to live in nests where parabiosis is verified (recognition of species that inhabit the same nest), since they imply sexual dimorphism.
